

Interconnection protection

of renewable and distributed generation

Juha Ylinen, Product Line Manager

Content

Introduction

- Renewables and Distributed Generation (DG)
- Why power systems are changing? What is the impact? How to manage the impact?

Connection rules

- Where and how to implement? Grid Code Examples. Islanding Detection

Interconnection Protection in DA Products

- Functionality and offering in Relion®

Interconnection protection of Renewable & Distributed Generation

Definition of renewable

Non-renewable energy sources

- Non-renewable energy is derived from finite natural resources that have developed for millions of years.
- Non-renewable energy sources are divided into fossil and nuclear fuels.
 - Fossil fuels include crude oil, natural gas and coal, and are all derived from organic matter, drilled for and pumped out or obtained by mining.
 - Nuclear fuels are primarily obtained by mining and refining uranium ore.

Renewable energy sources

- Renewable energy is derived from infinite natural resources, such as sunlight, wind, rain, tides, waves and geothermal heat.
- Renewable energy sources contribute to the energy mix in four main areas:
 - Electricity generation
 - Air and water heating/cooling
 - Transportation
 - Off-grid energy services in sparsely populated rural areas

Interconnection protection of Renewable & Distributed Generation

Examples of Finite and Renewable resources

Finite

Gas

Coal

Liquid Fuels

Nuclear

Renewable

Biogas

Geothermal

Hydro

Wave & tidal

Solar

Interconnection protection of Renewable & Distributed Generation

Renewable energy in electricity generation

Renewable energy sources

Wind power

- Capturing the air flow through wind turbines to convert the generated mechanical energy into electricity
- Reliable and consistent power generation from year to year but with significant variation on a shorter timescale

Hydropower

- Harnessing the power of moving water, typically by releasing water in dams constructed to store water
- Opening the reservoir releases water to flow through turbines to generate electricity

Biopower

- Using biomass to generate electricity
- Burning biomass to produce steam to spin a turbine and convert the generated mechanical energy into electricity

Solar power

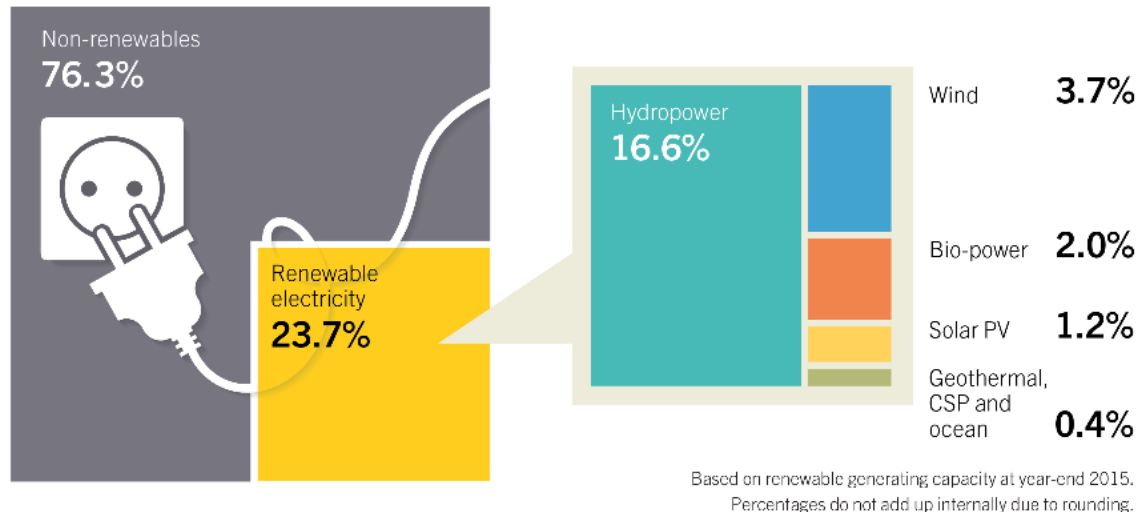

- Converting sunlight into electricity either directly by using photovoltaic (PV) cells or indirectly in concentrated solar power plants
- Used in both distributed generation and central-station, utility-scale power plants

Interconnection protection of Renewable & Distributed Generation

Renewable share and growth estimates

Global share estimates

Estimated Renewable Energy Share of Global Electricity Production, End-2015

Global growth estimates

Average Annual Growth Rates of Renewable Energy Capacity and Biofuels Production, End-2010 to End-2015

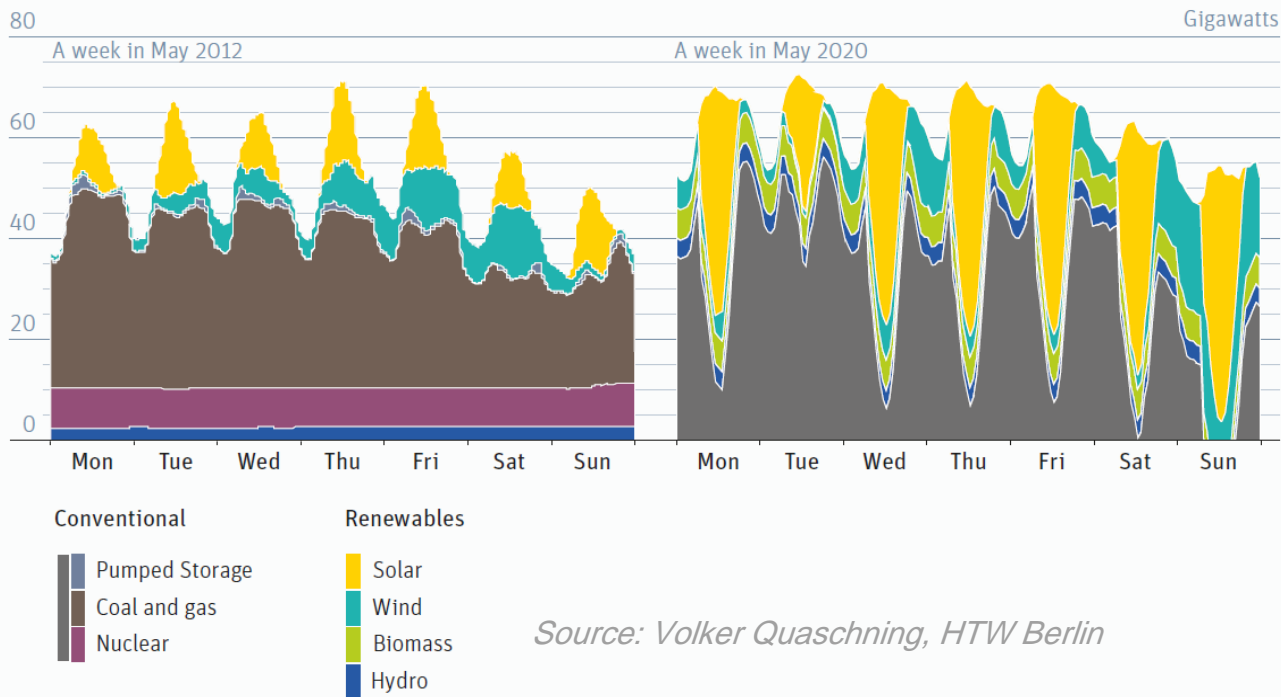

REN21 Renewables 2016 Global Status Report

Interconnection protection of Renewable & Distributed Generation

Renewable energy sources need flexibility

Estimated power demand over a week in 2012 vs. 2020, Germany

Source: Volker Quaschnig, HTW Berlin

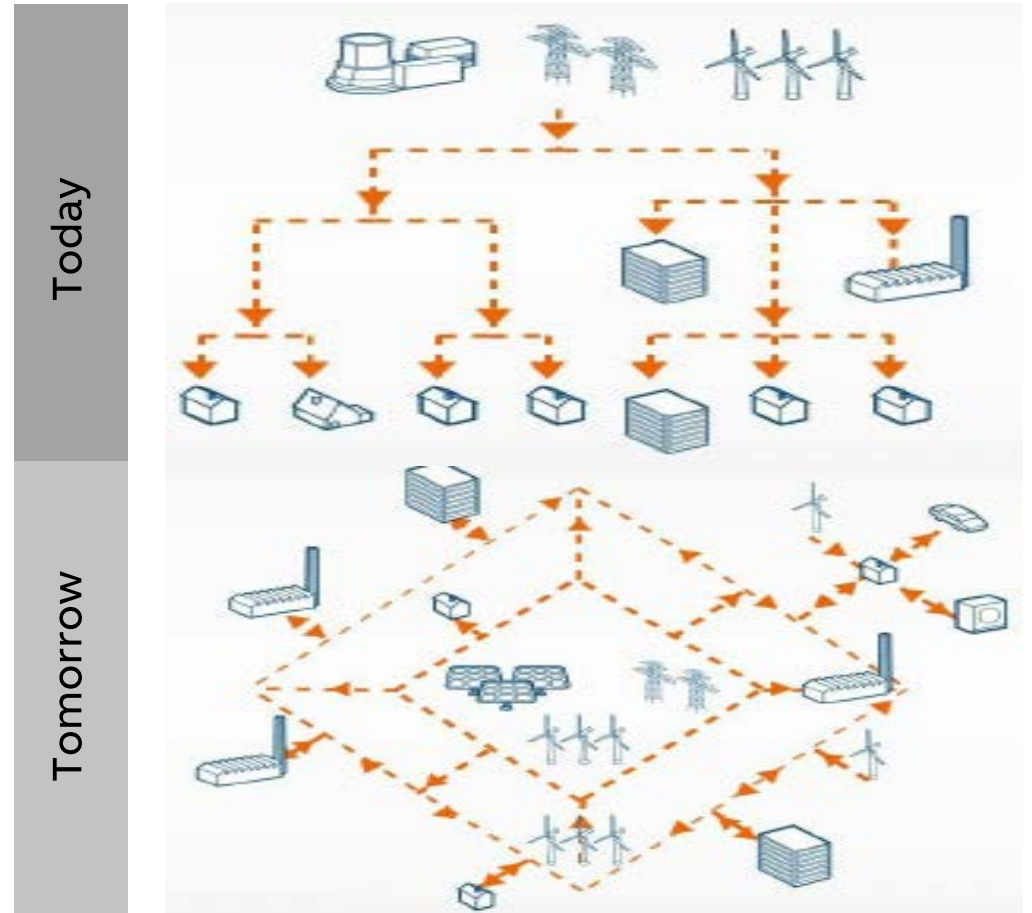

- Daily and even hourly variability of the Renewable based electricity generation will require even more flexibility in the future
 - From the demand (load)
 - From the backup sources

Interconnection protection of Renewable & Distributed Generation

Definition of Distributed Generation

DG is one part of DER

- **Distributed Energy Resources (DER)** is a wide definition
 - Controlling of customer loads
 - Distributed Generation
 - Battery storage systems
 - Electric vehicles
 - Onsite Generation
- Trend of increasing amount of DER's connected ongoing
- **Distributed Generation (DG)** characteristics
 - Produced closer to consumers, avoiding of the longer transmission of the energy
 - Several smaller size distributed instead of less larger size
 - Typically use renewable energy

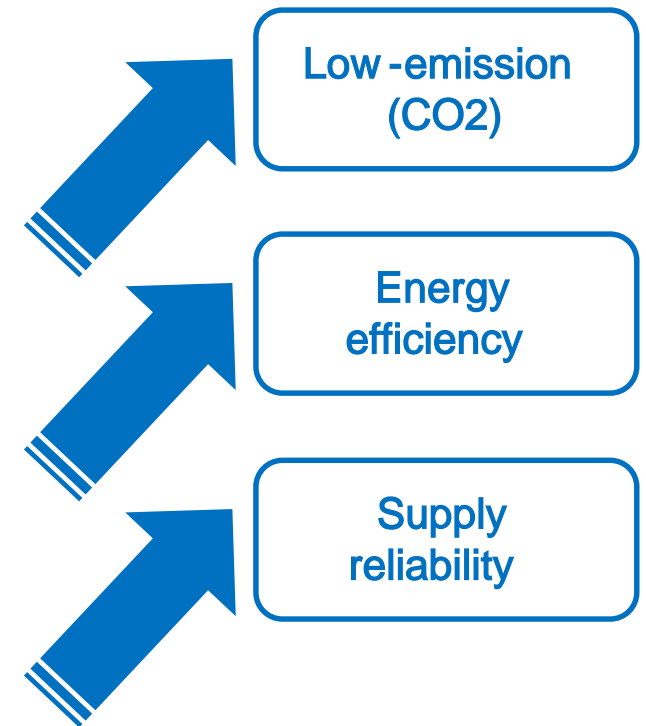

Interconnection protection of Renewable & Distributed Generation

Why power systems are changing?

Power systems are changing due to global drivers like

- 1) Climate change / environmental issues and
- 2) Increasing dependency on electricity and therefore there is a
 - Need for large-scale integration of renewable, **low -emission (CO₂)** energy sources in high-, medium- and low-voltage (HV, MV and LV) networks,
 - Need to improve **energy efficiency** of the whole energy system and
 - Need to improve electricity **supply reliability**

Interconnection protection of Renewable & Distributed Generation

What is the impact of these changes?

HV network

Large inverter-connected wind turbines connected to network

- Without rotational inertia
- With variable nature

Traditional power-plants reduced

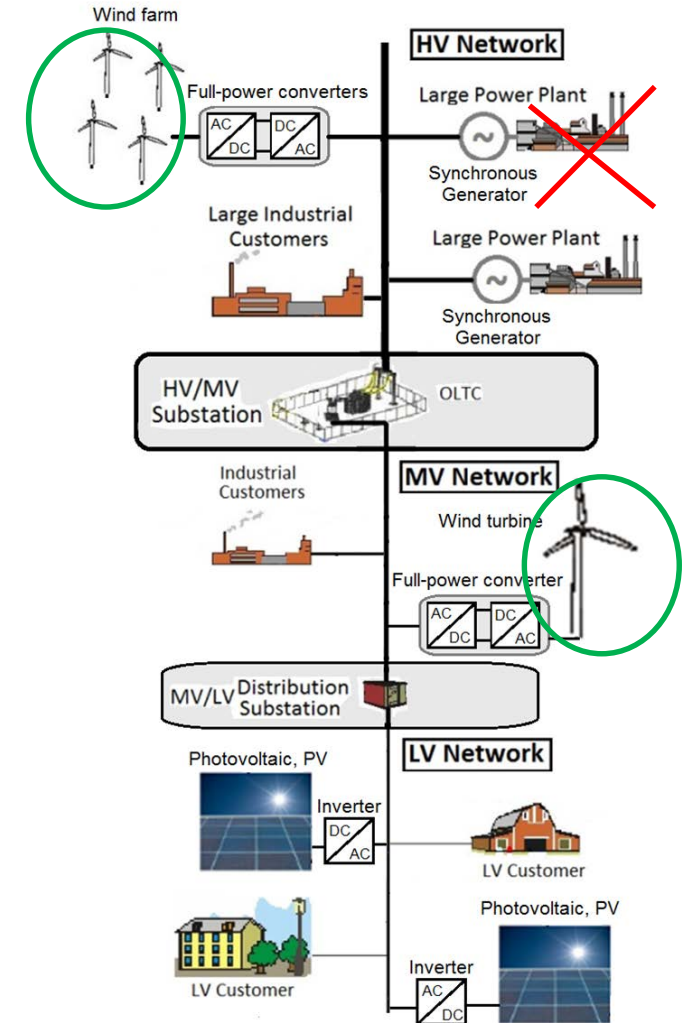

- Less inertia (rotating mass)
- Less frequency-, voltage- and power balancing support available
- More and Larger frequency and voltage variations
- HV network capacity constraints may become an issue

MV/LV network

Inverter-connected wind turbines and photovoltaics (PV) increasing amount

- Without rotational inertia
- With variable nature
- Traditional MV protection and Islanding detection may maloperate
- HV network stability issues are possible if large amount DG is simultaneously disconnected

Risk for stability issues

Interconnection protection of Renewable & Distributed Generation

What is needed to manage the impacts?

Previously

DG units have been required to be disconnected during utility grid faults / islanding situations

- Based on voltage, frequency, rate-of-change-frequency or vector shift
- Without any specific requirements to support utility grid (HV Network)

Grid Codes today for DG units

After the DGs amount has increased it has become more common to require HV network stability support from DGs

- Prevent unnecessary disconnection during HV network faults and frequency disturbances
- Support voltage and frequency during disturbances
 - P/f and Q/U control
 - Reactive current contribution during faults/ low voltage situations
 - Virtual inertia

Upcoming

In the future DER has potential for Active Network Management

- Frequency-, voltage- and power balancing support
- Improve energy efficiency i.e. reduce demand for network capacity and transmission losses
- Increase the reliability of electricity supply (e.g. micro grids)

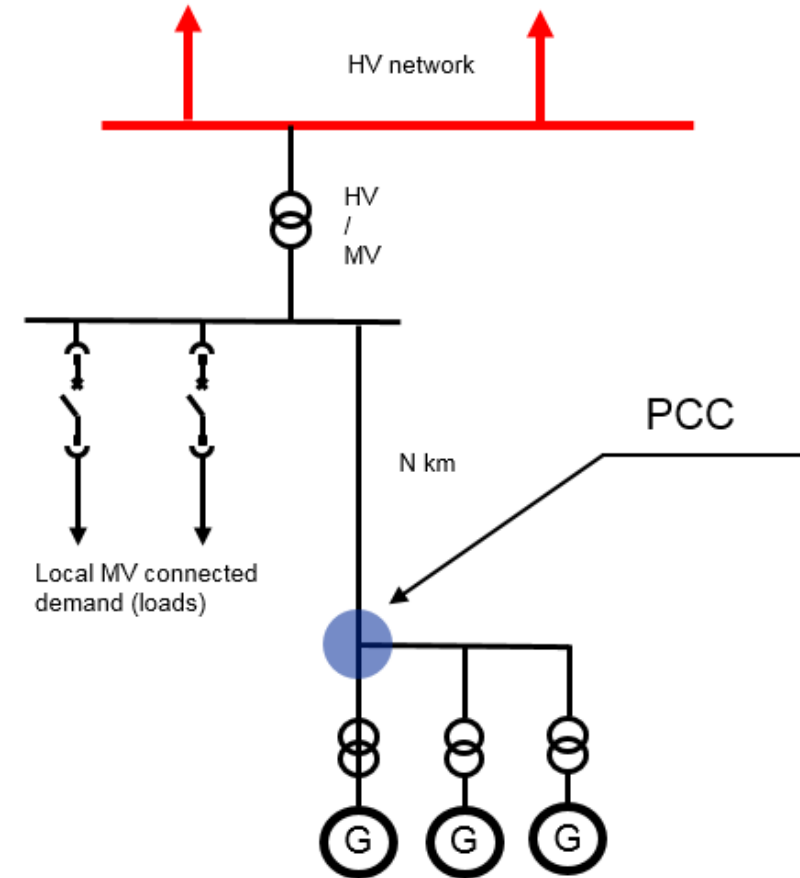

More advanced MV protection and Islanding detection methods

Interconnection protection of Renewable & Distributed Generation

Connection rules

DG unit Grid Code Requirements

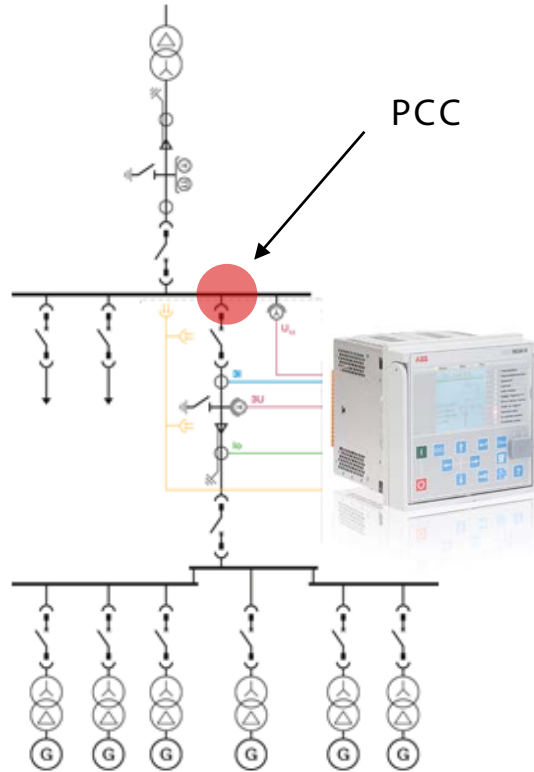

- Grid Codes are a technical specifications those facility connected into the public power system needs to fulfill at Point of Common Coupling (PCC)
 - Typically specifies the behavior of the generator under normal conditions as well as during disturbances
 - Traditionally required only for large conventional power plants
 - Increasing amount of DG's connected also to the lower voltage levels has created the need to revise and upgrade Grid Codes
- Grid Codes vary depending on country, type and size of generation unit
- International workgroups are targeting to harmonize different national Grid Codes, as an example ENSTO-E in Europe

Interconnection protection of Renewable & Distributed Generation

Definition of Interconnection protection

Interconnection Protection functions are fulfilling the grid codes at PCC

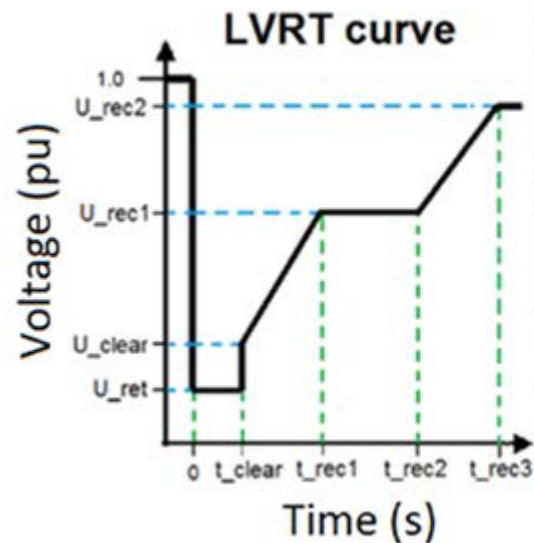

- Point of Common Coupling (PCC)
 - Is located in the substation where the Distributed Generation (DG) is being interconnected together with the grid
 - Sometimes also referred as Point of Common Connection or Point of Connection (PoC)
- Interconnection protection
 - Is a set of functions those are used together to fulfill the requirements defined by the grid codes for the PCC
 - Sometimes also referred as Intertie protection

Interconnection protection of Renewable & Distributed Generation

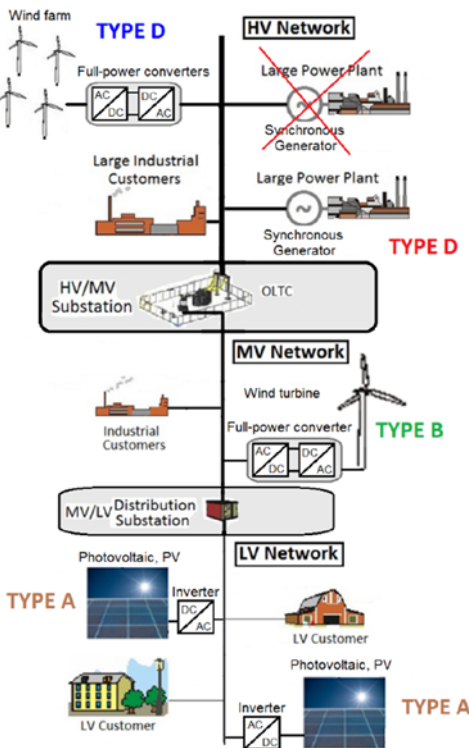

Grid Code Examples

Low-Voltage -Ride-Through (LVRT) Requirements for Different Types of DG Units

DG unit TYPE B AND C				
Synchronous generators				
U _{ret}	0.05 - 0.3	t _{clear}	0.14 - 0.25	
U _{clear}	0.7 - 0.9	t _{rec1}	t _{clear}	
U _{rec1}	U _{clear}	t _{rec2}	t _{rec1} - 0.7	
U _{rec2}	0.85 - 0.9 & ≥ U _{clear}	t _{rec3}	t _{rec2} - 1.5	
Converter based DG				
U _{ret}	0.05 - 0.15	t _{clear}	0.14 - 0.25	
U _{clear}	U _{ret} - 0.15	t _{rec1}	t _{clear}	
U _{rec1}	U _{clear}	t _{rec2}	t _{rec1}	
U _{rec2}	0.85	t _{rec3}	1.5 - 3.0	

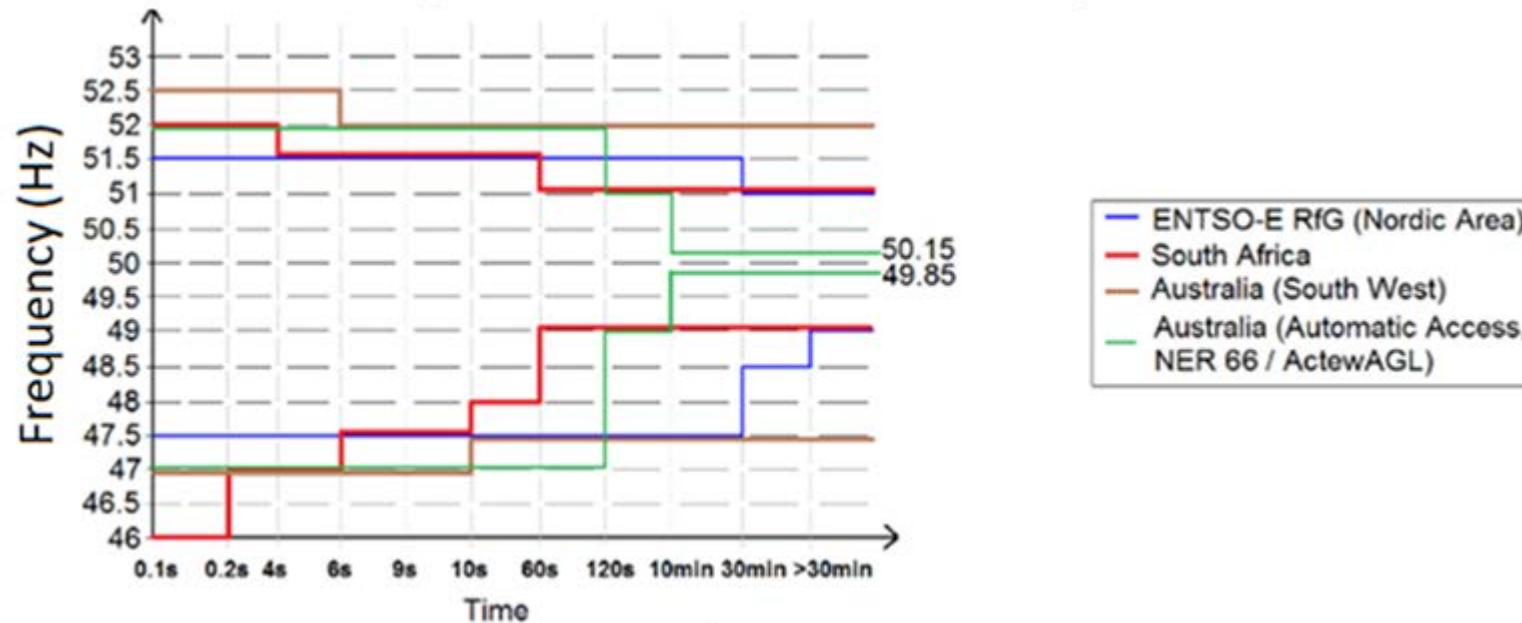

DG unit TYPE D				
Synchronous generators				
U _{ret}	0	t _{clear}	0.14 - 0.25	
U _{clear}	0.25	t _{rec1}	t _{clear} - 0.45	
U _{rec1}	0.5 - 0.7	t _{rec2}	t _{rec1} - 0.7	
U _{rec2}	0.85 - 0.9	t _{rec3}	t _{rec2} - 1.5	
DG unit TYPE D				
Converter based DG				
U _{ret}	0	t _{clear}	0.14 - 0.25	
U _{clear}	U _{ret}	t _{rec1}	t _{clear}	
U _{rec1}	U _{clear}	t _{rec2}	t _{rec1}	
U _{rec2}	0.85	t _{rec3}	1.5 - 3.0	

Interconnection protection of Renewable & Distributed Generation

Grid Code Examples

Frequency -Ride-Through (FRT) Requirements for Different Countries of DG Units

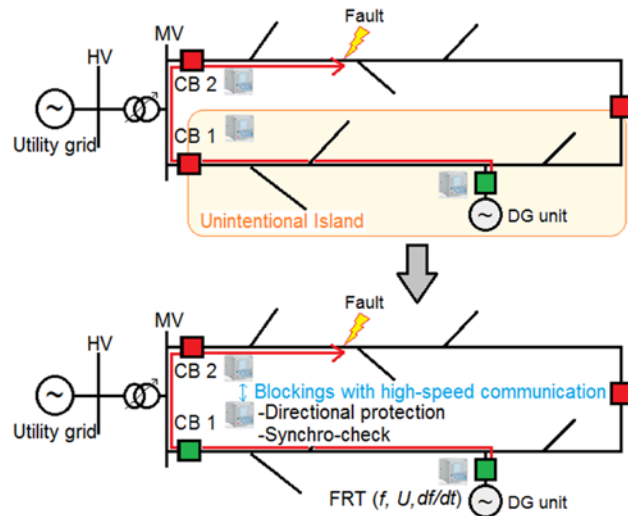

Interconnection protection of Renewable & Distributed Generation

Origin of Islanding Detection

Creation of "healthy island" by opening MV feeder CB due to

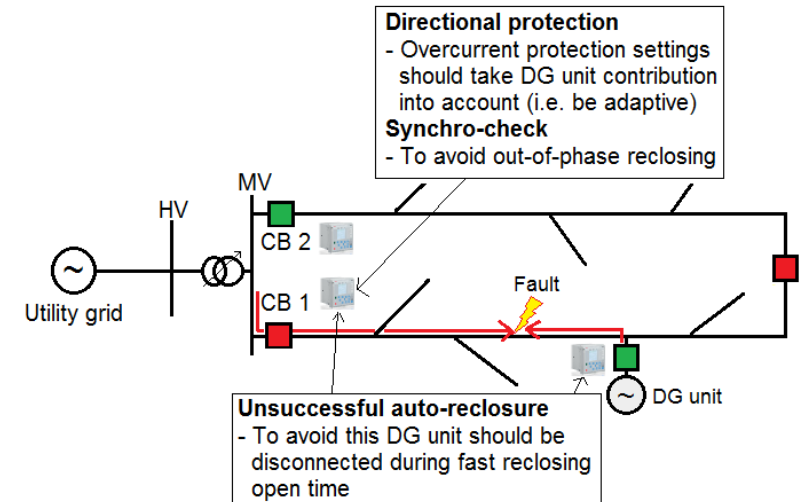

Fault at parallel MV feeder causing unwanted tripping of MV feeder

Or planned maintenance works at corresponding MV feeder

Creation of "faulty island"

For instance earth-fault at the corresponding MV feeder

Both "healthy" and "faulty" islanding situations should be detected

Interconnection protection of Renewable & Distributed Generation

Islanding Detection

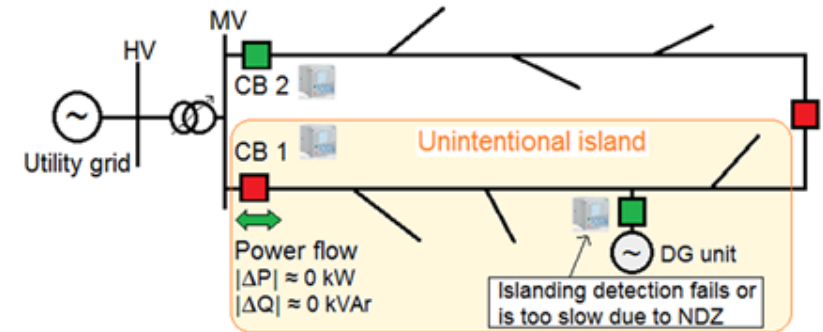

Traditional islanding detection techniques

- Communication-based (transfer trip)
- Local detection-based (active and passive)
 - Passive methods are frequency or rocof, Voltage or Voltage Vector Shift (VVS) based methods

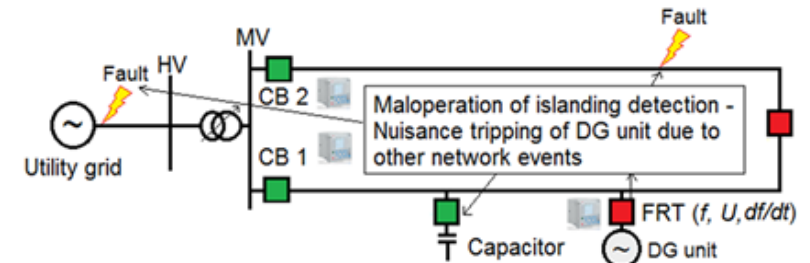

Other islanding detection techniques

- Hybrid (passive + active)
- Combined (communication + passive)

Common challenges of traditional passive methods

- Non-detection zone (NDZ) near a power balance

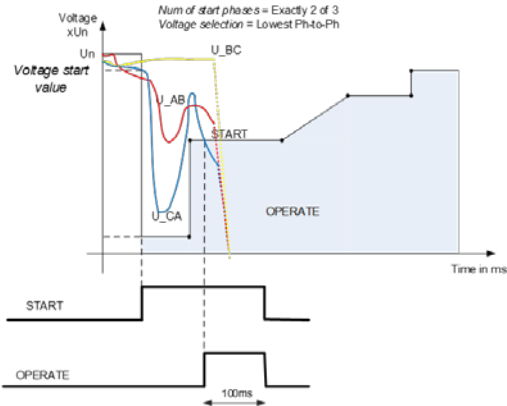

- Unwanted tripping due to other network events

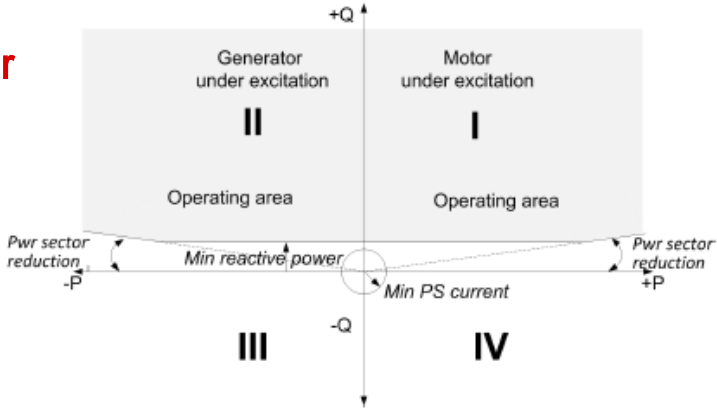

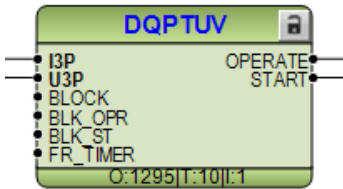

Interconnection protection of Renewable & Distributed Generation

Functionality in Relion[®] DA products

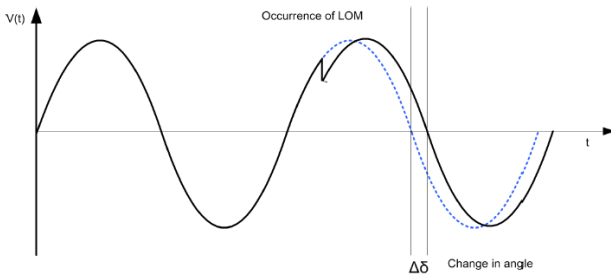

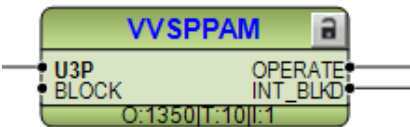

Low-voltage ride-through protection

Directional reactive power undervoltage protection

Voltage vector shift protection

++Engineering flexibility

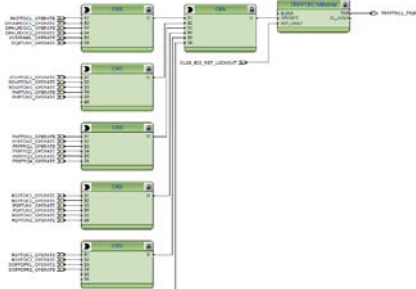

Table showing the settings for the ABB Relion DA products. The table is divided into two sections: Protection Settings and Communication Settings. The table lists various parameters and their values.

Parameter	Value
Protection Settings	
Directional Reactive Power Undervoltage Protection (DQPTUV)	
Operating Area	II
Motor Area	I
Generator Area	III
Communication Settings	
Communication Protocol	Modbus
Communication Address	1
Communication Baud Rate	9600
Communication Data Bits	8
Communication Stop Bits	1
Communication Parity	Even

Interconnection protection of Renewable & Distributed Generation
