

# HOW-TO GUIDE

## HOW TO USE THIRD-PARTY BLOCKS IN THE PLACE OF GLOBALS

“3rd party blocks” can be used instead of **Globals** in **Cylon BACnet** controllers, but some customers experienced difficulties with network traffic when replacing **Globals** directly. This document describes how to use **3rd party** blocks in the most efficient way.

### INTRODUCTION

---

#### What are “3<sup>rd</sup> Party blocks”?

The **3<sup>rd</sup> Party blocks** provide a mechanism for reading and writing values from and to a separate **BACnet** device directly in a **Strategy**. The same mechanism can also be used to access **BACnet** objects within the local **Strategy** if required.

There are two separate types of **3<sup>rd</sup> Party block** – one that is used to move data to and from analog **Strategy** block connections and one that is used to move data to and from binary **Strategy** block connections.

Both types of **3<sup>rd</sup> Party block** can access the same **BACnet** data, which is automatically converted to the appropriate data type as the data is pulled from or pushed to the network.

#### What is the difference between 3rd Party blocks and Globals?

**Globals** read and write point values on a schedule (Comms Controller service period) whether the point values change or not. **3<sup>rd</sup> Party blocks** can read at regular intervals in the same way, or they can write only when the point value changes.

**Globals** are implemented in strategies in 2 parts – a **Source global** block and a **Destination global** block. A single **3<sup>rd</sup> Party block** can read from or to a point in a **strategy** on another controller, to a point within the current **strategy**, or to any **BACnet** property on any other **BACnet** device.

**Note:** An important feature of the change-of-value **3rd-party block** approach, compared with **Globals** is that only one **strategy** needs to be downloaded in order to implement this approach, or to implement any change to it.

## Using 3<sup>rd</sup> Party blocks efficiently

Unlike Globals, 3<sup>rd</sup> Party blocks can send data whenever a point value changes. This means that network traffic can be reduced by placing the 3<sup>rd</sup> Party block in the **source strategy** rather than the **destination strategy**.

For example, a binary value representing occupancy can be sent from the **strategy** that contains the schedule to a **strategy** where the value is required, when the value changes – which is likely to be no more than twice per day.

As another example, if an analog value representing outside air temperature is being sent between **strategies**, the 3<sup>rd</sup> Party block can be set to send data only when the value changes more than a specified amount – which, if the Change-Of-Value (COV) level is properly set, could be significantly less often than a specified polling schedule.

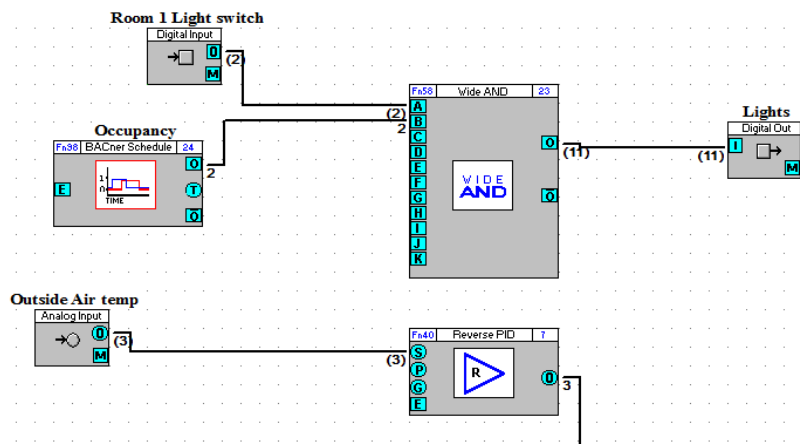

The latter example is illustrated on the following pages.

**Note:** While polling on larger networks is never recommended, on small or very lightly loaded networks polling can be used without a significant reduction in performance, and with a large interval could potentially reduce network traffic.

## SCHEDULED POLLING

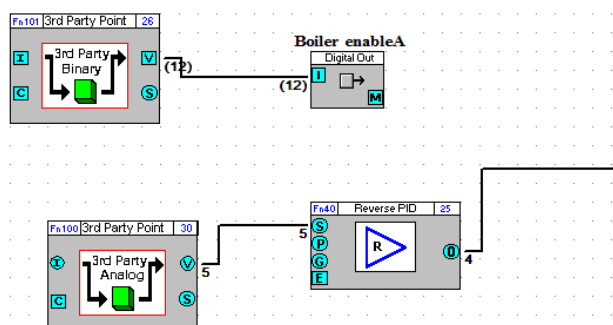

This scenario causes continuous network traffic and should be avoided :

### Source Source Strategy

### Destination Strategy

(3<sup>rd</sup> Party blocks polling remote data at regular intervals)

Third Party Analog Integration

Third Party Point Name: Outside Air temp

No.	Value
1	OFF

Point Addressing Info

Local ☐ Remote ☒

Device Instance Number: 264

Object Type: 0 - Analog Input

Object Instance: 3

Property: 85 - present-value

Writing

Write Priority: 16

☒ Relinquish on High To Low

COV Value: 0.000

Min. COV Time: 5

☒ COV Once High

☐ One Shot Write Low to High

☐ Time Once High: 5

Reading

Read Frequency: 30

☒ Default Value: 0.000

Third Party Digital Integration

Block Number: 27

Third Party Point Name: DnVn2

Name	PT No.	Value
Value In	2	OFF
Write Control	0	OFF

Point Addressing Info

Local ☐ Remote ☒

Device Instance Number: 264

Object Type: 3 - Binary Input

Object Instance: 12

Property: 85 - present-value

Writing

Write Priority: 16

☒ Relinquish on High To Low

COV Value: 1.000

Min. COV Time: 5

☒ COV Once High

☐ One Shot Write Low to High

☐ Time Once High: 5

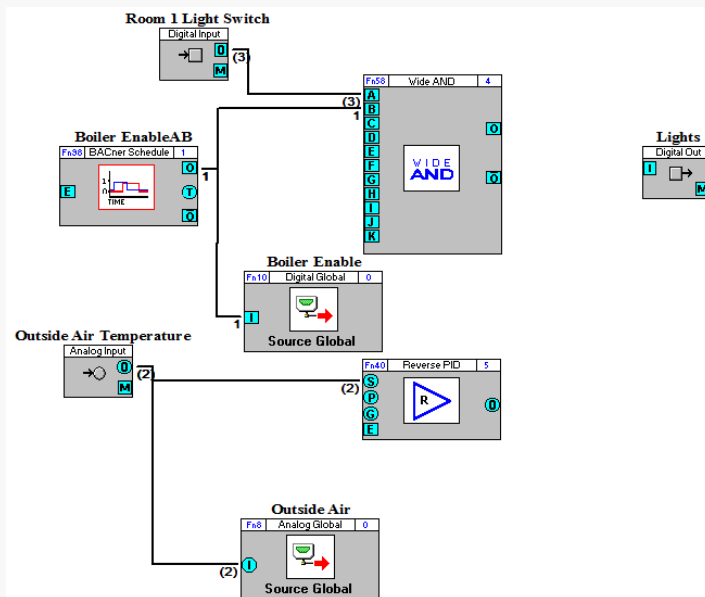

Reading

Read Frequency: 30

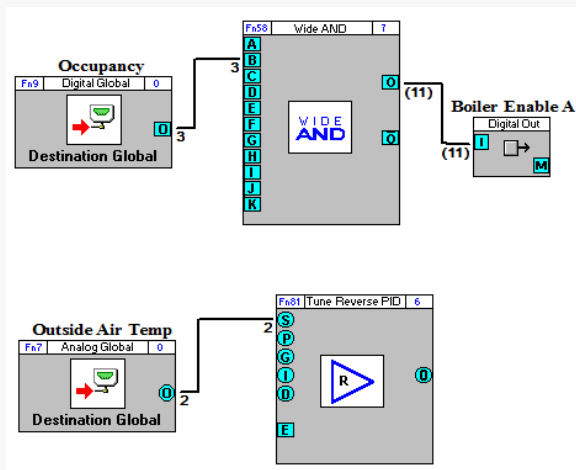

☒ Default Value: ☐

**Note:** The scheduled polling scenario is equivalent to the traditional Global method for transferring data, shown below:

### Source Source Strategy

### Destination Strategy

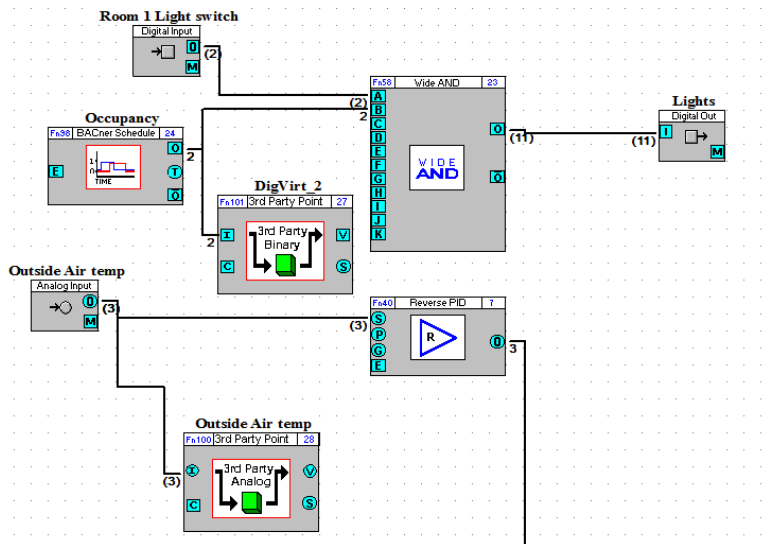

## TRANSMITTING DATA FROM SOURCE

To avoid scheduled polling, send values when they change, so that network traffic is caused only when the digital point changes state, or the analog value changes by a defined amount:

### Source Source Strategy

(3<sup>rd</sup> Party blocks transmitting on Change Of Value (COV))

Third Party Digital Integration
